Today:

**Feynman integrals and Fano and reflexive polytopes**

- ① Motivation
- ② Feynman integrals and polytopes
- ③ Fano and Reflexive polytopes
- ④ Summary and Outlook

# Feynman integrals in loop representation

- Feynman integral in **dim-reg** ( $D = 4 - 2\epsilon$ )

$$\hat{I}[\mathcal{N}(\boldsymbol{\ell}, \mathbf{k})] = \int \prod_{j=1}^L \frac{d^D \ell_j}{i\pi^{D/2}} \frac{\mathcal{N}(\boldsymbol{\ell}, \mathbf{k})}{\mathcal{D}_1 \cdots \mathcal{D}_E}$$

- Denominators

$$\mathcal{D}_e = (M_e)^{j_r} \ell_j \cdot \ell_r + 2(Q_e)^{j_r} \ell_j \cdot k_r + J_e + i\epsilon$$

- Numerators  $\mathcal{N}(\boldsymbol{\ell}, \mathbf{k})$ :

- Polynomials in  $W \equiv \{ \ell_i \cdot \ell_j, \ell_i \cdot k_j \}$
- Highest rank  $r$
- We impose momentum conservation on external momenta  $\mathbf{k}$

Example:  $L = 2$

$$\mathcal{N}(\boldsymbol{\ell}, \mathbf{k}) = c_1 k_1 \cdot k_2 + c_2 \ell_2^2 + c_3 (\ell_1 \cdot k_1)^2 + \cdots + c_n (\ell_1 \cdot \ell_2)^2$$

Highest rank is  $r = 4$

# Symanzik polynomials

- Construct matrices (Feynman parameters  $z_e$ )

$$\widetilde{M}^{jr} = \sum_{e=1}^E z_e M_e^{jr}, \quad \widetilde{Q}^{j\mu} = \sum_{e=1}^E z_e Q_e^{jr} k_r^\mu, \quad \widetilde{J} = \sum_{e=1}^E z_e J_e$$

- Symanzik polynomials

$$\mathcal{U} = \det(\widetilde{M}), \quad \mathcal{F} = \det(\widetilde{M}) \left( \widetilde{J} - (\widetilde{M}^{-1})^{ij} \widetilde{Q}^i \cdot \widetilde{Q}^j \right) / \mu^2$$

## Symanzik polynomials

- In Euclidean kinematics: invariants  $-(p_i + p_j)^2 > 0$
- Kinematic dependence is in  $\mathcal{F}$
- $\mathcal{U}$  homogeneous polynomial of degree  $L$
- $\mathcal{F}$  homogeneous polynomial of degree  $L + 1$
- $\mathcal{U}, \mathcal{F}$  positive functions of their parameters
- $\mathcal{U}$  and  $\mathcal{F}$  can only vanish on the boundaries of the integration region

# Feynman integrals in parametric representation

## Parametric representation

$$\hat{I}[\mathcal{N}(\boldsymbol{\ell}, \mathbf{k})] = \Gamma\left(E - \left\lfloor \frac{r}{2} \right\rfloor - \frac{LD}{2}\right) \int d^E z \delta\left(1 - \sum_{i \in A} z_e\right) \mathcal{U}^{E-D/2(L+1)-r} \mathcal{F}^{DL/2-E} \tilde{\mathcal{N}}(\mathbf{z})$$

- $\lfloor r/2 \rfloor$  denotes the nearest integer less or equal to  $r$ .
- $\deg(\tilde{\mathcal{N}}(\mathbf{z})) = rL$
- The numerator is a polynomial in  $E$  variables

$$\tilde{\mathcal{N}}(\mathbf{z}) = \sum_i c_i \mathbf{z}^{\mathbf{n}_i}$$

exponent vectors  $\in \mathbb{N}^E$

## Example

$$\begin{aligned} \tilde{\mathcal{N}}(\mathbf{z}) &= -(k_1^2 z_1 z_3 + k_3^2 z_2 z_3) \\ \mathbf{n}_1 &= (1, 0, 1), \mathbf{n}_2 = (0, 1, 1) \end{aligned}$$

## Cheng-Wu

- Cheng-Wu theorem allows us to choose  $A$  to be any nonempty subset of  $\{1, \dots, E\}$
- We choose the last edge  $A = \{E\}$

$$\hat{I}[\mathcal{N}(\ell, \mathbf{k})] = \Gamma\left(E - \left\lfloor \frac{r}{2} \right\rfloor - \frac{LD}{2}\right) \int d^{E-1}z \mathcal{U}^{E-D/2(L+1)-r} \mathcal{F}^{DL/2-E} \tilde{\mathcal{N}}(\mathbf{z})$$

- $\tilde{\mathcal{N}}(\mathbf{z})$  is not homogeneous anymore

$$\tilde{\mathcal{N}}(\mathbf{z}) = \sum_i c_i \mathbf{z}^{\mathbf{n}_i}$$

exponent vectors  $\in \mathbb{N}^{E-1}$

- We will consider each monomial at the time

# Newton Polytopes

- For a polynomial in  $E - 1$  variables in some monomials basis  $B$

$$f(\mathbf{z}) = \sum_{\mathbf{m} \in B} c_{\mathbf{m}} \mathbf{z}^{\mathbf{m}}$$

- Newton polytope is the convex hull of its exponent vectors

$$\text{Newton}(f) = \text{conv}(\text{supp}(f)) = \text{ConvexHull}(\mathbf{m}_1, \dots, \mathbf{m}_{|B|}) \in \mathbb{R}^{E-1}$$

- Sunset

$$\text{Newt}(\mathcal{F}) = \text{Newt}(m^2(z_1 z_2 + z_2 + z_1)(z_1 + z_2 + 1) - p^2 z_1 z_2)$$

# Representations of polytopes

- $V$ -representation: finite set of extreme points

$$P = \text{conv} \{ p_1, p_2, \dots \}$$

- $H$ -representation:  $M$  inequalities

$$P = \{ \mathbf{m} \in \mathbb{Z}^E \mid A\mathbf{m} - b \geq 0 \}$$

# Properties of Newton polytopes

- ①  $\text{face}_w(P) \equiv \{\mathbf{m} \in P \mid w \cdot \mathbf{m} \geq w \cdot v \text{ for all } v \in P\}$  proper or improper
- ② *relative interior* of a polytope  $P$ : the polytope with its proper faces removed
- ③ Minkowski sum:  $P + Q \equiv \{p + q \mid p \in P, q \in Q\} \subset \mathbb{R}^E$
- ④ scalar multiplication:  $\lambda P \equiv \{\lambda p \mid p \in P\}$ ,  $\lambda \in \mathbb{R}$
- ⑤  $f, g$  polynomials,  $n > 0$

$$\text{Newt}(fg) = \text{Newt}(f) + \text{Newt}(g)$$

$$\text{Newt}(f^n) = n \text{Newt}(f)$$

Example:

$$V : \text{Conv}\{(0, 1), (1, 0), (0, 2), (2, 0)\}$$

$$H : \begin{pmatrix} 1 & 1 \\ 0 & 1 \\ 1 & 0 \\ -1 & -1 \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} - \begin{pmatrix} 1 \\ 0 \\ 0 \\ -2 \end{pmatrix} \geq 0$$

# Convergence of tensor integrals

- Feynman integrals are Euler-Mellin integrals studied by Berkesh-Forsgård-Passare, '13

- One monomial at the time

$$\hat{I}[\mathcal{N}(\ell, \mathbf{k})] \sim \sum c_i \int d\eta_{E-1} \frac{z^{\mathbf{m}_i+1}}{\mathcal{U}^{r-E+D/2(L+1)} \mathcal{F}^{E-DL/2}}, \quad d\eta_{E-1} = \frac{dz_1}{z_1} \dots \frac{dz_{E-1}}{z_{E-1}}$$

## Theorem (Berkesh-Forsgård-Passare)

- Let  $n_{\mathcal{U}} \equiv r - E + D/2(L + 1)$ ,  $n_{\mathcal{F}} \equiv E - DL/2$
- Assume that Symanzik polynomials are non-vanishing on region of integration, full dimensional  $n_{\mathcal{U}} > 0$ ,  $n_{\mathcal{F}} > 0$ ,
- Feynman polytope (full-dimensional)

$$P_F = n_{\mathcal{U}} \text{Newt}(\mathcal{U}) + n_{\mathcal{F}} \text{Newt}(\mathcal{F})$$

- BFP: The integral converges and defines an analytic function in the Mandelstam invariants and in the domain for the exponents

$$\{ \mathbf{m} \in \mathbb{C}^E \mid \mathbf{m} + \mathbf{1} \in \text{relint}(P_F) \}$$

## Toy example: rank-1 finite numerator in four dimensions

- Kinematics

$$k_1 \neq k_3, \quad k_1^2 \neq 0, k_3^2 \neq 0, \quad k_2^2 = 0$$

- Parametric representation

$$\hat{I}_{\Delta,r} = \sum_{\mathbf{m} \in B} c_{\mathbf{m}}(\mathbf{s}) \int \frac{d^3 z z^{\mathbf{m}+1}}{z_1 z_2 z_3} \frac{\delta(1 - \sum_i z_i)}{\mathcal{U}^{-3+D+r} \mathcal{F}^{-D/2+3}}$$

- Symanzik polynomials

$$\mathcal{U} = z_1 + z_2 + z_3 \quad \mathcal{F} = -(k_1^2 z_1 z_3 + k_3^2 z_2 z_3)$$

- Feynman polytope

$$P_{\Delta} = (r + D - 3) \text{Newt}(\mathcal{U}) + (3 - D/2) \text{Newt}(\mathcal{F})$$

## Toy example: rank-1 finite numerator in four dimensions

- Set  $r = 1$

$\mathbf{m} + 1 = (1, 1) \Rightarrow \mathbf{m} = \mathbf{0} \Rightarrow (z_1^0 z_2^0)$  is a "finite monomial"

- General numerator of rank 1

$$\mathcal{N}(\ell, \mathbf{k}) = c_1 \ell \cdot k_1 + c_2 \ell \cdot k_2$$

free coefficients  $c_i$

- In parametric representation

$$\mathcal{N}(z, \mathbf{k}) = \frac{1}{2} c_1 (k_3^2 - k_1^2) z_2 - c_1 k_1^2 + \frac{1}{2} c_2 (k_1^2 - k_3^2)$$

- Coefficients of **non-finite** monomials must vanish

$$c_1 = 0 \Rightarrow \mathcal{N} = \ell \cdot k_2 \text{ is a rank-1 finite numerator}$$

Full story: **Finite integrals from Feynman polytopes**, DLC-Kosower-Novichkov, *Phys. Rev. D* **111** (2025) no.10, 105013

- ① Motivation
- ② Feynman integrals and polytopes
- ③ Fano and Reflexive polytopes**
- ④ Summary and Outlook

# Fano and reflexive polytopes

Fano polytope Nill '05, Kasprzyk '12

A lattice polytope is (canonical) Fano if the only lattice point that lies strictly in its interior is the origin.

- Let  $N$  be the dual lattice to  $M$  with respect to the scalar product  $\langle \bullet | \bullet \rangle : M \times N \rightarrow \mathbb{Z}$
- Using this scalar product we can define the dual (or polar) polytope  $\nabla := \{ \mathbf{b} = (b_1, \dots, b_n) \in N \mid \langle \mathbf{a}, \mathbf{b} \rangle \geq -1, \forall \mathbf{a} \in \Delta \} \subset N \cong \mathbb{Z}^n$

Reflexive polytope

A lattice polytope  $\Delta$  is reflexive if its polar polytope  $\nabla$  is a lattice polytope and has a single interior point. The polytopes  $(\Delta, \nabla)$  are said to be mirror pairs.

# Reflexive polytopes

- Reflexive polytopes appear in String Theory to construct Calabi-Yau varieties
- Classified up to 4-dimensions Maximilian Kreuzer and Harald Skarke

**Complete classification of reflexive polyhedra in four-dimensions**, Kreuzer-Skarke, *Adv. Theor. Math. Phys.* 4 (2000) 1209

- There are 473,800,776 reflexive polyhedra in four dimensions

## Observation

Feynman polytope with a single interior point  $\mathbf{p}$  is finite if it satisfies BFP theorem

$$I_F \sim \int d\eta_{E-1} \frac{z^{\mathbf{p}}}{\mathcal{U}^{n_U} \mathcal{F}^{n_{\mathcal{F}}}}, \quad d\eta_k := \frac{dz_1}{z_1} \cdots \frac{dz_k}{z_k}$$

## Question:

Is there a way to determine how many polytopes are reflexive for a given Feynman graphs and/or for all Feynman graphs?

# What on earth are Calabi-Yau varieties?

- In cartoons!

1 loop

2-loop and beyond

2-loop and beyond

# Banana integrals: the Verrill class of polytopes

- Banana integrals in two dimension are the basic examples where reflexive polytopes arise

$$\mathcal{U}_L = z_1 z_2 \cdots z_{L+1} \left( \frac{1}{z_1} + \cdots + \frac{1}{z_{L+1}} \right)$$

$$\mathcal{F}_L = \mathcal{U}_L (m_1^2 z_1 + \cdots + m_{L+1}^2 z_{L+1}) - s z_1 \cdots z_{L+1}$$

- For banana integrals  $N = L + 1$  and in  $d = 2$  one has

$$P_{\mathcal{F}} = \text{Newt}(\mathcal{F})$$

- The classical period

$$I_L \sim \int d\eta_L \frac{1}{1 - t\phi_L(x)}$$

Reflexive polytopes for the sunset at 2 and 3-loop

# How many are there?

- Inspired by Kreuzer-Skarke <sup>also Fanosearch project</sup>: fix number of dimensions  $\sim$  edges

$N = \dim + 1$	graph topologies	Fano classes	reflexive classes	non-reflexive Fano classes
2	1	1	1	0
3	2	2	2	0
4	3	3	3	0
5	6	4	4	1
6	13	8	7	4
7	28	11	6	6
8	70	23	11	16
9	193	36	14	24
10	565	104	26	88

# N-gon class: Calabi-Yau ?

- For  $L = 1$  the polytope is the scaled standard simplex

$$N\Delta_{HS}^{N,1}$$

- The polar polytope the polar polytope has the simple expression

$$P_F^\circ = \text{Conv}\left\{e_1, e_2, \dots, e_{N-1}, -\sum_{i=1}^{N-1} e_i\right\}$$

- Nonvanishing Hodge numbers for  $N$ -gon. In all cases  $h_{11} = 1$ .

$N$	4	5	6	7	8	9	10
$h_{1N-3}$	19	101	426	1667	6371	24229	92278

- Encodes projective space  $\mathbb{P}^{N-1}$
- Quintic  $N = 5$

$$P_F = \text{Conv}\left\{(-1, -1, -1, -1), (4, -1, -1, -1), (-1, 4, -1, -1), \right. \\ \left. (-1, -1, 4, -1), (-1, -1, -1, 4)\right\}$$

# Singular CYs

- 1-loop graphs are expected to evaluate in terms of polylogs so the surface is degenerate
- Example ( $y_{ij}$  are dual momentum variables)

$$\phi_{\Delta} = z_1 y_{21}^2 + z_2 y_{21}^2 + \frac{z_1 y_{31}^2}{z_2} + \frac{y_{31}^2}{z_2} + \frac{z_2 y_{32}^2}{z_1} + \frac{y_{32}^2}{z_1}$$

$$\phi_{\text{sunset}} = m_1^2 z_1 + m_2^2 z_2 + \frac{m_2^2 z_2}{z_1} + \frac{m_1^2 z_1}{z_2} + \frac{m_3^2}{z_1} + \frac{m_3^2}{z_2}$$

- Naively they are both elliptic, however

$$1/t_{\Delta} = y_{12}^2 + y_{13}^2 + y_{23}^2, \quad 1/t_{\text{sunset}} = s - (m_1^2 + m_2^2 + m_3^2)$$

- This can also be compared against the vacuum case of the sunset, see section 3 of Ref. [Bloch et'al, '2013](#).

One take home message

Polytopes can teach us about the hidden geometry of Feynman integrals

# Evaluation of integrals

- We observe that integrals with a reflexive polytope are simple to evaluate

The wheel with three spokes ( $6\zeta(3)$ )

The diamond circle graph ( $36\zeta(3)^2$ )

Two graphs that evaluate to zeta values

- Integrals which have associated a Fano polytope are not, for example

- So we gave up quickly

- ① Motivation
- ② Feynman integrals and polytopes
- ③ Fano and Reflexive polytopes
- ④ Summary and Outlook

# Summary and Outlook

## Summary

- Convergence of Feynman integrals is controlled by math's theorem  
*Berkesch-Forsgård-Passare, 13'*
- We can construct systematically locally finite numerators in parametric and loop space
- A new class of reflexive polytopes arise in 1-loop  $N$ -gons (unexpected Calabi-Yau geometries)
- Reflexive and Fano polytopes arising from Finite Feynman integrals are sparse

## Outlook

- Finite integrals with certain Fano geometries as bases
- Machine Learning finiteness and reflexivity

Thank you!
